HYPOTHYROIDISM

A BOOKLET FOR PATIENTS AND THEIR FAMILIES

A publication of the American Thyroid Association (ATA)
www.thyroid.org

COPYRIGHT 2013 AMERICAN THYROID ASSOCIATION
THE AMERICAN THYROID ASSOCIATION (ATA)

The American Thyroid Association (ATA) is the leading organization devoted to thyroid biology and to the prevention and treatment of thyroid disease through excellence in research, clinical care, education, and public health.

ACKNOWLEDGEMENTS

The ATA gratefully acknowledges the current and past members of the ATA Clinical Affairs Committee and the ATA Patient Education & Advocacy Committee as contributors and authors to this booklet; all educational information for patients and the public posted on the ATA website www.thyroid.org; as well as articles and updates disseminated through Friends of the ATA and the Clinical Thyroidology for Patients.

ATA PATIENT RESOURCES

The ATA patient resources are designed to provide up-to-date information for thyroid patients, their families and other interested public communities. The ATA is dedicated to serving as an educational resource for the public by supporting thyroid research and promoting the prevention, treatment and cure of thyroid-related diseases and thyroid cancer.

The information contained in or made available through the ATA Website www.thyroid.org is not intended to replace the services of a trained health professional or to be a substitute for medical advice of physicians. The user should consult a physician in all matters relating to his or her health, and particularly in respect to any symptoms that may require diagnosis or medical attention.

The American Thyroid Association makes no representations or warranties with respect to any information offered or provided within or through the ATA Website regarding treatment, action, or application of medication. Neither the ATA nor any of its Affiliates will be liable for any direct, indirect, consequential, special, exemplary, or other damages arising therefrom.

HYPOTHYROIDISM

WHAT IS THE THYROID?

The thyroid is a butterfly-shaped endocrine gland usually located in the lower front of the neck below the larynx (the voice box). The thyroid’s job is to make thyroid hormones, which are secreted into the blood and then carried to every tissue in the body. Thyroid hormone helps the body use energy, stay warm and keep the brain, heart, muscles, and other organs working as they should. The main hormone made by the thyroid is thyroxine, also called T4 because it contains four iodine molecules. Small amounts of another and more potent thyroid hormone containing three iodine molecules, triiodothyronine (T3) are also made by the thyroid gland. However, most of the T3 in the blood is made from T4 in other body tissues.

Thyroid hormones control the way every tissue in your body uses energy. They are essential to help each cell in your body’s tissue and organs work right. For example, thyroid hormone controls the body’s temperature, heart rate, blood pressure, and the rate at which food is turned into energy (metabolism).

WHAT IS HYPOTHYROIDISM?

Hypothyroidism is a kind of thyroid disease. If you have hypothyroidism that means you have an underactive thyroid ("hypo-" means "under" or "below normal"). In people with hypothyroidism, the thyroid does not make enough thyroid hormone to keep the body running normally. Common causes of hypothyroidism are autoimmune disease, surgical removal of the thyroid, and radiation treatment.

Low thyroid hormone levels cause the body's functions to slow down, leading to general symptoms like dry skin, fatigue, loss of energy, and memory problems. Hypothyroidism is diagnosed by a simple blood test for thyroid-stimulating hormone (TSH). Hypothyroidism is treated by replacing the missing thyroid hormone with synthetic thyroxine pills, which the person must take every day for life. With daily treatment, most patients recover completely.

WHO CAN DEVELOP HYPOTHYROIDISM?

Hypothyroidism is one of the most common thyroid diseases. It affects people all over the world—of every age, sex, race, and level of wealth and education.

About 2-3 percent of Americans have hypothyroidism and as many as 10-15% have mild hypothyroidism. More than half of those with hypothyroidism do not know they have it.
FACTORS CONTRIBUTING TO RISK OF DEVELOPING HYPOTHYROIDISM:

- Have a close relative, such as a parent or grandparent, with an autoimmune disease
- Hypothyroidism can develop at any age, but risk for developing it increases with age.
- Hypothyroidism is more common in women than men; and, much more so in young women than young men. The risk of hypothyroidism increases during pregnancy, after delivery and around menopause.
- Hypothyroidism is more common in whites and Asians than in other races and ethnicities.
- Have another autoimmune disorder, such as type 1 diabetes, rheumatoid arthritis, multiple sclerosis, celiac disease, Addison's disease, pernicious anemia, or vitiligo
- Have been treated with radioactive iodine or received radiation to the neck or upper chest
- Have had thyroid surgery
- Have Down syndrome or Turner syndrome – genetic disorders
- Have bi-polar disease (manic depression)

SYMPTOMS

Hypothyroidism has a variety of symptoms. Symptoms are something you see, feel and/or experience yourself. Many of these symptoms are often confused with other health conditions.

When your thyroid hormone levels are too low, your body's cells cannot get enough thyroid hormone. This causes your body's processes to start slowing down. For example, the body makes less heat and less energy, causing organs like the brain and bowels to move more slowly. As the body slows, you may notice that you feel colder, you tire more easily, your skin is getting drier, you're becoming forgetful and depressed, and you've started getting constipated.

So hypothyroidism doesn't just cause symptoms; it can make other conditions worse.

Symptoms of hypothyroidism usually appear slowly over several months or years. However, some people develop symptoms of hypothyroidism quickly over a few months. In general, the lower your thyroid hormone levels become and the longer they stay low, the more severe your symptoms will be.

Subclinical (mild) hypothyroidism may cause mild symptoms or no symptoms at all. Severe hypothyroidism usually causes severe symptoms.

Some people are very sick by the time they learn their diagnosis; others whose blood tests show severe hypothyroidism have few if any symptoms. Because the symptoms are so variable, the only way to know for sure if you have hypothyroidism is through blood tests.
COMMON FEATURES OF HYPOTHYROIDISM

- Less energy
- More fatigue, trouble awakening in the morning, need for more sleep, and tendency to fall asleep during the day
- Feeling cold when other people feel warm
- Less sweating
- Drier, itchier skin
- Drier, coarser, more brittle hair
- More hair loss (the amount differs in different people; patients don't go bald but their hair can look thin)
- Loss of appetite
- Mild weight gain (5-20 pounds) and difficulty losing weight (hypothyroidism doesn't cause obesity)
- New or worsening problems with memory, slower thinking
- New snoring
- Muscle cramps and joint aches
- New feeling of pins and needles in the hands and feet (paresthesia)
- New or worsening constipation
- Puffiness around the face (especially the eyes), hands, ankles, and feet because of fluid build-up
- Carpal tunnel syndrome
- Heavier and/or more frequent menstrual periods, worse cramps, worse premenstrual symptoms, milky discharge from the breasts
- Feeling irritable
- New or worsening depression-sadness or not caring about anything
- New or worsening hoarse voice
- New or worsening hearing loss
- Goiter (swelling in the front of the neck, caused by enlargement of the thyroid)
- Slowing of heart rate
- Slightly higher blood pressure
- Higher cholesterol levels
- Growth delay in children

If you have hypothyroidism, you may also have body changes that you cannot feel. For example, you may not know that cholesterol is building up in your blood or that plaque is hardening your arteries, both of which can increase your risk for heart attack. Hypothyroidism does not just cause symptoms; it can make other health conditions worse.

No one can predict exactly which symptoms a person will develop or how severe the symptoms will be. Some people have many symptoms by the time they are diagnosed with hypothyroidism. Others have few, if any, symptoms.

Because the symptoms are so variable, the only way to know for sure whether you have hypothyroidism is with blood tests.
CAUSES

There are many reasons why the cells in the thyroid cannot make enough thyroid hormone. Here are the major causes, from the most to least common:

AUTOIMMUNE DISEASE

The immune system normally protects the body against bacterial and viral "invaders." In autoimmune diseases ("auto" means "self"), the immune system attacks a normal part of the body. In autoimmune hypothyroidism, the immune system accidentally attacks cells in the thyroid. This causes the cells to become inflamed and damaged, interfering with their ability to make thyroid hormone. When enough thyroid cells have been destroyed, too few are left to meet the body's need for thyroid hormone.

Autoimmune thyroid disease is more common in women than men. It can start at any age, but becomes more common as people get older. In women, it often begins during pregnancy, after delivery, or around menopause. The cause is likely a combination of an inherited tendency and an as yet unknown trigger. Autoimmune hypothyroidism can begin suddenly, but in most people it develops slowly over years.

The most common form of autoimmune hypothyroidism is called Hashimoto’s disease. This can sometimes cause the thyroid to shrink over time.

SURGICAL REMOVAL OF PART OR ALL OF THE THYROID

Some people with thyroid nodules, thyroid cancer, or Graves' disease need to have part or the entire thyroid removed. Hypothyroidism results when the entire thyroid is removed or when the remaining thyroid tissue no longer works properly.

RADIATION TREATMENT

Some people with Graves' disease, nodular goiter, or thyroid cancer are treated with radioactive iodine (\(^{131}\)I). Radioactive iodine destroys the thyroid, which can result in hypothyroidism. Hodgkin's disease, lymphoma, or cancers of the head or neck are treated with radiation which can destroy the thyroid and result in hypothyroidism.

CONGENITAL (FROM BIRTH) HYPOTHYROIDISM

About 1 in 4,000 babies each year are born without a thyroid or with a partly formed thyroid. A few babies have part or their entire thyroid in the wrong place (ectopic thyroid). In some babies, the thyroid cells or their enzymes do not function correctly or are affected by medications taken by the mother. In others, the thyroid may make enough hormone for a while but later stops functioning as the child gets older or becomes an adult. In the United States, all children are tested at birth for hypothyroidism.
THYROIDITIS

Thyroiditis is an inflammation of the thyroid. It is usually caused by an autoimmune attack (such as Hashimoto’s disease, postpartum thyroiditis or silent thyroiditis) or by a viral infection. Thyroiditis can make the thyroid release its whole supply of stored thyroid hormone into the blood at once, causing the thyroid to become overactive (hyperthyroidism) for a brief period of time. Once the entire stored hormone has been released, the thyroid becomes underactive. Almost all people with viral thyroiditis recover their thyroid function, but about one-fourth of people with autoimmune thyroiditis have permanent hypothyroidism.

MEDICINES

Some medicines can interfere with the thyroid’s ability to make thyroid hormone, leading to hypothyroidism. Lithium is one of the most common medicines that cause hypothyroidism. Others medicines that can cause hypothyroidism are amiodarone, interferon alpha, and interleukin-2. All of these drugs are most likely to trigger hypothyroidism in people who have a genetic tendency to autoimmune thyroid disease. Rarely, some people with the blood cancer multiple myeloma who are treated with thalidomide can develop hypothyroidism.

TOO LITTLE OR TOO MUCH IODINE

The thyroid must have iodine to make thyroid hormone. Iodine comes into the body in foods, mainly dairy products, chicken, beef, pork, fish, and iodized salt. The iodine then travels through the blood to the thyroid. Keeping thyroid hormone production in balance requires the right amount of iodine. People who live in undeveloped parts of the world may not get enough iodine in their diet. Worldwide, iodine deficiency is the most common cause of hypothyroidism, although it is a rare cause in the U.S. Too much iodine can also cause or worsen hypothyroidism. The major source of too much iodine is dietary supplements containing kelp, a kind of seaweed. Most of these supplements are sold with the false promise of helping people lose weight. Other sources of too much iodine are x-ray dyes, medicines like amiodarone, and some older expectorants (medicines that help clear the lungs and throat).

DAMAGE TO THE PITUITARY GLAND

The pituitary gland tells the thyroid how much hormone to make. If the pituitary gland is damaged by injury, a tumor, radiation, or surgery, it may no longer be able to give the thyroid the right instructions, and the thyroid may stop making enough hormone.
PREVENTION

In countries where the diet does not contain enough iodine, taking iodine supplements can prevent hypothyroidism. In the United States and other developed countries, where most people's diet contains enough iodine, there is no known way to prevent hypothyroidism.

Diagnosing hypothyroidism early by testing newborn babies, pregnant women, and people with symptoms or risk factors is the best way to prevent it from worsening. The biggest risk factor is having relatives with thyroid disease.

DIAGNOSIS

A diagnosis is the art or act of identifying a disease from its signs and symptoms. A healthcare professional, ideally a physician, considers several factors when identifying or determining the nature and cause of hypothyroidism, including:

- Your symptoms (changes in how you feel), medical history, risk factors, and family history
- A physical exam
- Blood tests: The most sensitive test is TSH. In some circumstances, other tests, such as free T4, free T4 index and total T4 may be helpful.

CHANGES IN HOW YOU FEEL

Hypothyroidism cannot be diagnosed based on symptoms alone. Most hypothyroid symptoms are common complaints that many people with a normally functioning thyroid can have. These symptoms might be clues to conditions that may or may not be related to the thyroid. One way to help figure out whether your complaints are symptoms of hypothyroidism is to think about whether you have always had a symptom or whether the symptom is a change from the way you used to feel (hypothyroidism could be indicated).

MEDICAL AND FAMILY HISTORY

Tell your doctor everything you can at your appointment. This includes information about:

- Your overall health, especially changes in your health
- Your family’s health history, especially if a close relative (such as a parent or grandparent) has hypothyroidism or another form of thyroid disease
- If you have ever had thyroid surgery
- If you have ever had radiation to your neck to treat cancer
- If you are taking any medicines that can cause hypothyroidism, such as amiodarone, lithium, interferon alpha, interleukin-2, or thalidomide

PHYSICAL EXAM

In addition to listening to your symptoms and your medical history, your doctor will check
your thyroid and look for physical signs of hypothyroidism, such as:

- Dry skin
- Swelling
- Slower reflexes
- Slower heart rate

## TSH AND T4 BLOOD TESTS

Your doctor may order one of the blood tests described here:

### TSH TEST

TSH (thyroid-stimulating hormone) is the most important and sensitive test for diagnosing and monitoring hypothyroidism. TSH is a simple blood test that measures how much T4 the thyroid is being asked to make. An abnormally high TSH test may mean you have hypothyroidism.

**WHAT IS TSH (THYROID-STIMULATING HORMONE)?**

Your thyroid needs to be told how much thyroid hormone to make. The instructions come from the pituitary gland. The system works as a feedback loop: special cells in your pituitary gland determine the normal T4 range for your body. This is known as your set point. As blood flows through your pituitary gland, these cells measure your T4 levels to determine whether they are at your set point.

The pituitary cells communicate with your thyroid by sending their own hormone, TSH (thyroid-stimulating hormone), into the blood. When your T4 levels are at your set point, the pituitary gland sends out enough TSH to tell the thyroid to keep making the same amount of T4. If the T4 levels get low, the pituitary sends out more TSH to tell the thyroid to make more T4. The lower the T4 levels go, the higher the TSH goes. The opposite is also true: if the T4 levels get too high, the pituitary sends out less TSH, telling the thyroid to make less T4.

### NORMAL AND ABNORMAL TSH LEVELS (mU/L)

<table>
<thead>
<tr>
<th>TSH LEVELS MEASURED THROUGH BLOOD TESTS:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0 – 0.4</td>
</tr>
<tr>
<td>0.4 – 4.0</td>
</tr>
<tr>
<td>4.0 - 10.0</td>
</tr>
<tr>
<td>10.00 +</td>
</tr>
</tbody>
</table>

- hyperthyroidism or suppressed TSH
- normal range of TSH
- subclinical (mild) hypothyroidism
- hypothyroidism

In most labs, the normal range for TSH is 0.4 mU/L to 4.0 mU/L. If the TSH measures above 4.0 mU/L on both a first test and a repeat test, this may indicate hypothyroidism. Most people whose thyroid works normally have a TSH between 0.4 mU/L and 4.0 mU/L. This
range may be lower in pregnant women and higher in older people. If your TSH is between 2.5 and 4.0 mU/L your doctor may wish to test your blood for anti-thyroid peroxidase (anti-TPO) antibodies. If you have these antibodies, you may have an autoimmune thyroid disorder which is a risk factor for developing hypothyroidism. If so, you should have the TSH test repeated at least once a year. There is no need to repeat a positive anti-TPO test. Some physicians may want to reevaluate a previously reported negative anti-TPO test in connection with a pregnancy.

Remember: as the T4 falls, the TSH rises (as the thyroid hormone supply falls, the demand increases). As the T4 rises, the TSH falls (as the supply rises, the demand falls).

There is one exception to the rule that everyone with hypothyroidism has a high TSH. If the pituitary stops working properly, it may not be able to send out normal amounts of TSH. In this case, even though the thyroid itself may be healthy, if it does not get enough TSH, it won't make enough T4. This disorder is called secondary, or central, hypothyroidism. Fortunately, it is rare.

T4 TESTS

T4 (thyroxine) is produced by the thyroid gland. The free T4 and the free T4 index are both simple blood tests that when combined with a TSH test offer results that tell how your thyroid is functioning.

WAYS THAT HYPOTHYROIDISM CANNOT BE DIAGNOSED

- **Low body temperature** is not a reliable measure of hypothyroidism. People with hypothyroidism as well as people who do not have hypothyroidism can have temperature well below 98.6 degrees F.
- **Reflexes** may be slowed in hypothyroidism, but in many other conditions, too.
- **Saliva tests** for thyroid disease are not accurate.
- **Swelling in the base of the neck**: An underactive thyroid may look like a normal thyroid or it may be larger or smaller. Even if your thyroid looks normal, you can have thyroid disease.
TREATMENT

THYROXINE (T4) REPLACEMENT

Hypothyroidism cannot be cured but it can be treated and, in most people, completely controlled. Hypothyroidism is treated by replacing the amount of hormone that your own thyroid can no longer make. This makes sure that your T4 and TSH stay at normal levels. Synthetic thyroxine (also called L-thyroxine or levothyroxine) pills contain hormone like the T4, which a healthy thyroid makes naturally. Synthetic thyroxine must be taken every day for life.

Like the T4 that your own thyroid makes, each dose of synthetic thyroxine keeps working in your blood for about a week. This lets the T4 levels in your blood stay steady so a constant supply of T4 is available to your body cells. (Thyroxine takes about 4 weeks to clear completely from the body.)

WHO SHOULD TREAT YOU

Many people with hypothyroidism can be treated effectively by their primary care doctor. You might need to see an endocrinologist or thyroidologist for a second opinion or for regular care if:

- You have congenital hypothyroidism or another unusual cause for your hypothyroidism
- You are pregnant
- You have autoimmune polyglandular syndrome—autoimmune hypothyroidism combined with one or more other autoimmune conditions, such as type 1 diabetes, Addison’s disease, or premature ovarian failure
- You have another condition, like epilepsy, heart disease, or bowel disease that affects the treatment of your hypothyroidism
- You have trouble establishing the right dose of thyroxine
- You have many questions and concerns that your regular doctor cannot answer

Most people with hypothyroidism can be treated as outpatients without any hospitalizations.

THYROXINE DOSE FACTORS

When you are first diagnosed with hypothyroidism, your doctor will determine your starting dose of thyroxine based on:

- Weight: the more you weigh, the higher your dose usually is
- Age: older people should start on a low dose and raise it slowly to give their body time to adjust with special attention to heart health. Because older people’s bodies clear drugs more slowly, they generally stay on lower doses. Special considerations also apply to children.
- Cause of hypothyroidism: if your thyroid has been removed, all of your T4 must be
replaced with thyroxine. If your hypothyroidism is caused by autoimmune disease and is still making some T4, you may only need a low dose of thyroxine. If you have had thyroid cancer, you may need a higher-than-usual dose of thyroxine to keep your TSH near zero and prevent the cancer from coming back

- Other health conditions you have: if you have impaired intestinal absorption diseases such as Celiac or Crohn’s, or if you have had bariatric surgery, you may have trouble absorbing thyroxine and may need a higher dose
- Other medicines you are taking: if you take birth control pills, hormone replacement therapy, antidepressants, anti-seizure or anticonvulsant medications, Zoloft®, Tegretol®, Dilantin®, Phenobarbital, proton pump inhibitors to reduce stomach acid production, or dietary supplements, such as calcium, iron or soy, you may need a higher dose of thyroxine. If you take testosterone or niacin, you may need a lower dose of thyroxine

Your starting dose is your doctor’s best estimate of the amount of thyroxine you need. Your doctor may purposely start you on a low dose to prevent you from getting symptoms of too much thyroxine, like anxiety, restlessness, nervousness, and a racing heart. The doctor may then raise your dose gradually. Over time your thyroxine dose may need to be adjusted. Because thyroxine is a slow-acting hormone, it may take several weeks before your body adjusts and you start to feel their effects. After about 6 to 10 weeks, your body will have adjusted enough that your doctor can test your TSH again to see whether your TSH has gone down.

Every person responds differently to thyroxine, and you may need a higher or lower dose than someone who started out with the same TSH as you. You will eventually reach a stable dose, and you may stay on that dose for many years.

Thyroxine comes in multiple strengths, each with its own pill color. When you get your pills, make sure you have been given the right strength.

Many people have to take two thyroxine pills—sometimes of two different strengths—to get the right dose. If your dose needs to be 163 mcg, your doctor might give you prescriptions for 75 mcg pills and for 88 mcg pills. Taken together, they equal 163 mcg.

Getting the right dose for you is just a matter of taking your pills as prescribed and getting regular blood tests. A small change in your thyroxine dose can make a big change in how you feel and function. If you are on the right dose, all your symptoms caused by hypothyroidism should disappear.

**TAKING YOUR THYROXINE PILLS**

What’s most important is that you start treatment right away and remember to take your pill every day – every day. Your doctor might prescribe that you take the same dose every day or different doses on different days. Following these instructions allows your doctor to accurately measure how your TSH is responding to treatment.

Thyroxine replaces the hormone that your thyroid can no longer make. Thyroxine is not like
an antibiotic that you take for a week or two weeks until your infection is treated. The only way to control your hypothyroidism is to take your pill every day for the rest of your life. If you stop taking your pills for any reason, your hypothyroidism will return.

Some people who have hypothyroidism without any symptoms say that they do not want to take pills because they feel fine. They still need to be treated because their body functions are slowing down even if they cannot feel it.

**TIPS FOR TAKING YOUR THYROXINE PILLS**

These tips may help you take your pills everyday:

- Take your pill at the same time every day—first thing in the morning or last thing at night works well for many people—and make it part of your daily routine. For example, you may remember to take your pill if you take it before or after brushing your teeth.
- For many people, it is easy to forget whether they have taken their daily pill. To keep better track of your pills, store them in a container that has a box marked for each day of the week. Whatever container you use, keep it tightly closed so your pills stay dry.
- Store your pills in the room where you will best remember to take them. As with all medicines, keep thyroxine out of the reach of children.
- You can take your pill with any liquid except soy milk. Cow's milk is probably fine. Grapefruit juice and coffee should be avoided. Do not try to swallow your pill without liquid; if it dissolves in your mouth or throat, not enough medicine will be absorbed into your blood.
- It does not matter whether you take your pill on an empty stomach or with food, as long as you always do the same thing. That is because foods and medicines can interfere with the body's ability to absorb thyroxine. If you always take your pill with food, you may need a higher dose than if you always take it on an empty stomach.
- Wait 4 hours after taking thyroxine before you eat foods that contain soy (including soy formula for babies), take calcium supplements, iron supplements, or antacids that contain either calcium or aluminum hydroxide, or take other medicines such as cholestyramine (Questran®, colestipol (Colestid®), or sucralfate (Carafate®).

**GIVING THYROXINE TO BABIES**

To give thyroxine to a baby, crush the thyroxine pill between two spoons, mix it with a little water or breast milk, and immediately squirt it inside the baby's cheek with a medicine dropper. Then, nurse or bottle-feed the baby. Do not try to crush the thyroxine pill and mix it into in a bottle. Thyroxine loses its strength in liquid.

**GIVING THYROXINE TO CHILDREN WHO CANNOT SWALLOW PILLS**

You can give a thyroxine pill to a child the same way as a baby—crush the thyroxine pill between two spoons, mix it with a little water, and immediately squirt it inside the baby's cheek with a medicine dropper. Or, put the pill in a small paper cup with just enough water to dissolve the pill and have the child drink the solution. Then, put a little more water in the cup
to catch any more bits of the pill and have the child drink that.

WHY YOU SHOULD ALWAYS TAKE THE SAME BRAND OF THYROXINE

The available brands of thyroxine are Synthroid®, Levothroid®, Unithroid® tablets, and Tirosint® gel capsules. The U.S. Food and Drug Administration (FDA) regulates all of these brands. All are safe and effective.

Each brand contains the same active ingredient, but each is made a little differently. Because these small differences affect the way that the body absorbs the drug, the FDA has not ruled that these products are interchangeable (it is not safe to substitute one for another). If you change from one brand to another, even at the same dose, your body may absorb and respond to it differently. This means that if you switch to a new drug, you need a TSH test 6 to 12 weeks later and your new dose may need to be adjusted.

The American Thyroid Association recommends that once you get used to one brand of thyroxine, you continue with that brand. The ATA also recommends that you use brand name drug rather than a generic drug. This is because generic drugs can be substituted with other generic drugs from different manufacturers of levothyroxine each time you get your prescriptions refilled. Make sure the pharmacist gives you the same brand each time you pick up your pills.

IF YOU MISS A PILL

It is not serious to miss just one pill because thyroxine stays in your blood for a long time. For example, if you remember this afternoon that you did not take your pill this morning, take it now. If today you remember that you did not take yesterday’s pill, you can take two pills in one day—if possible, take one of the pills in the morning and the other one in the evening.

If you are sick and vomit up a pill, do not take an extra pill. Wait and take your next regular dose tomorrow. However, if you vomit up a pill because you are pregnant and having morning sickness, take another pill at bedtime when you are less likely to feel sick.

It is much more serious to miss one thyroxine pill every week. This is because your body will react as though are you taking a lower dose than needed. For example, suppose you are prescribed 100 mcg of thyroxine a day; this adds up to 700 mcg of thyroxine a week. If you miss one pill every week, you would only be taking 600 mcg of thyroxine a week, or 86 mcg of thyroxine a day. If you miss two pills every week, you are taking only 500 mcg of thyroxine a week, or 71 mcg of thyroxine a day. If you miss several thyroxine pills, do not try to make it up. Just start over with daily pills and figure out how best remember to take them.

Keep track of how often you miss your thyroxine pills so you can tell your doctor next time your TSH is tested.
IF YOU BECOME PREGNANT

If you become pregnant, take your thyroxine dose as prescribed. Thyroxine is safe for women who are pregnant. In fact, if you are pregnant, you need thyroxine more than ever because it provides T4 for both yourself and your developing baby.

You should see your doctor as soon as you find out you are pregnant or even before becoming pregnant if possible. You and your doctor will work closely throughout your pregnancy to ensure the best possible health for yourself and your baby. Your doctor should test your TSH several times while you are pregnant. You may raise your thyroxine dose by as much as 30 to 50 percent because your body needs more T4 to handle the physical demands of pregnancy. After the baby is born, your body returns to needing the same amount of T4 as before you got pregnant.

Many experts recommend that all women get tested for thyroid disease if they are thinking of becoming pregnant or as soon as they learn that they are pregnant. If you are diagnosed with hypothyroidism during your pregnancy, you must begin thyroxine treatment right away and continue treatment and testing at least every 6 to 8 weeks until you deliver. Then your TSH levels will determine whether you need to continue treatment.

TREATMENT CONSIDERATIONS

SHOULD SUBCLINICAL (MILD) HYPOTHYROIDISM BE TREATED?

Subclinical (mild) hypothyroidism is defined as a T4 in the normal range with a slightly high TSH that ranges from 4.0 to 10.0 mU/L. Subclinical hypothyroidism usually causes few or no symptoms. Experts have not come to an agreement on whether to treat people, including children, with subclinical hypothyroidism although some Pediatricians believe treating children offers special benefits.

Some doctors treat all people with subclinical hypothyroidism. Some treat only people who have symptoms. Some treat those with anti-TPO antibodies or a high cholesterol. Some do not treat people with subclinical hypothyroidism but instead test them on a regular basis to see whether their TSH rises higher.

Research is still needed on whether people with subclinical hypothyroidism stay healthier if they are treated or whether their health is at risk if they are not treated (it is possible that even subclinical hypothyroidism can increase people's risk for heart problems). However, there is no harm in treating people with subclinical hypothyroidism, as long as they are given the correct thyroxine dose.

People with a TSH in the high-normal range of 2.6 and 4.0 mU/L may wish to keep being tested to see whether their levels rise to the level of hypothyroidism.
HOW HELPFUL ARE TREATMENTS COMBINING T4 WITH T3?

A healthy thyroid makes 14 times as much T4 as T3. T4 is turned into T3 by normal bodily processes. When tissue cells remove T4 from the bloodstream, they change some of it into T3. In fact, more than 80% of the T3 in your blood is made from T4 that has been changed by the liver and other tissues outside the thyroid. Underactive thyroids still make both T4 and T3—just not enough. Because the failing thyroid still makes some T3, and because body tissues turn some T4 into T3, most hypothyroid patients need to be treated only with T4. Most people with hypothyroidism need to be treated only with T4. In these patients, having the right amount of T4 allows the body to make the right amount of T3.

All brand-name thyroxine pills in the United States contain only T4. However, some researchers have wondered whether a combination of T4 and T3 might be better. Early studies have shown that some people felt better on the combination, but the improvement did not last. Unlike thyroxine pills, which work for a week, the only FDA-approved brand of T3 works in the body for just a few hours. This means that people taking T3 need several doses a day. Another problem is that taking T3 pills interferes with the body's normal ability to adjust T3 levels, so the T3 levels that the pills give to people cannot match the body's normal patterns. This makes some people feel worse on combined therapy. A T4-T3 combination might be of some help to people who have had their whole thyroid removed and cannot make any T4 or T3 of their own. If people want to try a combination of T4 and T3 combination, the ATA recommends that their doctor give them at most 5 mcg of T3 twice a day, and, in turn, reduce their T4 dose. Taking too much T3 can seriously harm the heart.

THYROXINE FROM ANIMALS

Before synthetic forms of thyroxine became available, animal thyroid saved many lives. Now, people are safer taking synthetic thyroxine. Some people argue that pills made from animal thyroids are more natural, but these pills pose several dangers.

- Pills made from animal thyroid are not purified. They contain some proteins that do not normally appear in the human bloodstream. Thyroxine made in a lab is exactly the same hormone that a human thyroid makes, but in a pure form.
- The balance of T4 to T3 in animals is not the same as in humans, so the hormones in animal thyroid pills are not necessarily natural for the human body.
- The amounts of T4 and T3 can vary in every batch of animal thyroid, making it harder to keep both hormones level.
- Case reports suggest possible allergic reactions tied to components within animal thyroid preparations.

In sum, synthetic thyroxine is much safer than animal thyroid.

THYROXINE AND WEIGHT LOSS

Hypothyroidism can cause a mild weight gain of 5 to 20 pounds, but does not cause obesity. People who have gained a lot of weight should find the real cause. People with hypothyroidism who are started on the right thyroxine dose will not suddenly lose weight,
but they should find it easier to lose weight if they try. People who take too high of a thyroxine dose in the hope of rapid weight loss can weaken their muscles and bones and damage the heart—all of which can make it harder to exercise. Worse yet, a high dose of thyroxine can cause increased hunger. So instead of losing weight, people may gain weight.

People with a normal TSH should never take thyroxine pills for weight loss.

**INEFFECTIVE TREATMENTS**

Chinese herbs, selenium, iodine-tyrosine supplements, kelp (a kind of seaweed), and other herbal remedies high in iodine may promise to treat hypothyroidism, but they do not work. Once the thyroid stops functioning, taking extra iodine or other substances will not help it work better. In fact, taking too much iodine can worsen both hypothyroidism and hyperthyroidism. Worse yet, taking these can prevent people from getting the thyroxine treatment that they really need.

**SIDE EFFECTS AND COMPLICATIONS OF TREATMENT**

The only dangers of thyroxine are caused by taking too little or too much. If you take too little, your hypothyroidism will continue. If you take too much, you can develop the symptoms of hyperthyroidism—an overactive thyroid. The most common symptoms of too much thyroid hormone are fatigue, the inability to sleep, greater appetite, nervousness, shakiness, feeling hot when other people are cold, muscle weakness, shortness of breath, and a racing, skipping heart. Hyperthyroidism can also cause changes that you cannot feel, like bone loss (osteoporosis) and an irregular heartbeat.

People who have hyperthyroid symptoms should have their TSH tested. If it is below normal, their thyroxine dose needs to be lowered.

People who have had thyroid cancer need to take higher-than-usual thyroxine doses. This increases their risk for bone loss. If you are being treated with thyroxine following thyroid cancer, you should take plenty of calcium through food and supplements. Your doctor should also monitor your bone density regularly.

Thyroxine pills do not harm the thyroid gland.

**FOLLOW-UP**

**REPEAT BLOOD TESTS**

After a change in your thyroxine dose, you will need to have your TSH checked about every 6 to 10 weeks. You may need tests more often if you are pregnant or you are taking a medicine that interferes with your body’s ability to use thyroxine. The goal of treatment for hypothyroidism is to get your TSH in the normal range and keep it there. The American Thyroid Association recommends that your doctor try to keep your TSH within a narrow
range of 0.5 to 2.0 mU/L. Within this range, your body gets the best possible amount of thyroxine and you are likely to feel the best.

Babies must get all their daily treatments and have their TSH levels checked as they grow to prevent mental retardation and stunted growth (cretinism).

---

**NORMAL VARIATION IN TSH LEVELS**

TSH levels can vary, even when you are taking the same dose of thyroxine. Do not worry if you get a result of 0.8 mU/L on one TSH test and 1.1 mU/L on your next test. It does not mean that your hypothyroidism is getting worse. Differences in test results are expected:

- TSH levels can vary because the pituitary sends out TSH in pulses rather than a steady stream.
- Labs cannot measure every test exactly the same way. For example, if a lab runs two tests on one blood sample, it may get two slightly different results.
- TSH levels normally go up at night and come down during the day. There is some evidence that T4 levels also vary slightly throughout the day.

---

**BE SURE TO FOLLOW UP WITH YOUR DOCTOR IF…**

Once you have established the thyroxine dose right for you, TSH tests are necessary about once a year. You need to make an appointment to discuss with your physician if you:

- Feel a change in your symptoms. If your TSH turns out to be high, hypothyroidism is probably causing your symptoms. But if your TSH is normal, it means something else is causing your symptoms.
- Want to change your thyroxine dose or brand, or change to taking your pills with or without food.
- Gain or lose a lot of weight without changing your diet or exercise routine. For some people, even a change of 10 pounds or less can signal that something is wrong.
- Start or stop taking a drug that can interfere with absorbing thyroxine, or you change your dose of such a drug (see "How your thyroxine dose is decided," above). For example, if you start taking estrogen in a birth control pill or in hormone replacement therapy, you may need to raise your dose. If you stop taking the drug, you may need to lower your dose.
- Are not taking your thyroxine pill every day. It is very important to be truthful when telling your doctor how many pills you have missed. If you have missed pills but say that you have taken them as prescribed and if your TSH test is then high, your doctor may think that your hypothyroidism is getting worse and may raise your thyroxine dose.
- Want to try to stop thyroxine treatment. If ever you think you are doing well enough not to need thyroxine treatment any longer, try it only under your doctor's close supervision. Rather than stopping your pills completely, you might ask your doctor to try lowering your dose. If your TSH increases, you will know that you need to continue treatment. You should never stop thyroxine treatment on your own. You must take your thyroxine every day, most likely for the rest of your life.
American Thyroid Association • Hypothyroidism

IF HYPOTHYROIDISM IS NOT TREATED OR IF TREATMENT IS STOPPED

BABIES AND CHILDREN

Thyroid hormone is essential for the brain to develop normally. In a healthy pregnancy, the women’s thyroid supplies the developing baby with thyroid hormone during the first trimester. In the second trimester, the developing baby's thyroid starts to make its own hormone. Once babies are born, they must depend completely on their own thyroid.

Too little thyroid hormone can keep the brain from developing normally. If the pregnant woman has hypothyroidism, she cannot give her developing baby enough thyroid hormone. When a woman with untreated or undertreated hypothyroidism delivers a baby who has a normal thyroid, the baby's IQ may be a few points lower than it would have been otherwise, but the child is not at increased risk for birth defects. If a baby does not get enough thyroid hormones, it cannot maintain normal thyroid hormone levels before or after birth.

Hypothyroidism that begins before birth and through the age of 3, when left untreated, puts babies and children at risk for mental retardation. Untreated severe hypothyroidism slows both brain development and physical growth (cretinism). In the United States and some other developed countries, all babies are tested for hypothyroidism a few days after birth so that they can be diagnosed and begin treatment right away, if hypothyroid.

HYPOTHYROIDISM CAUSED BY IODINE DEFICIENCY

The body needs iodine to make thyroid hormone. People who live in parts of the world where they do not get enough iodine from their food may develop hypothyroidism. This, in turn, puts babies and children at risk for mental retardation. Untreated severe hypothyroidism slows both brain development and physical growth (cretinism). In the United States and some other developed countries, all babies are tested for hypothyroidism a few days after birth so that they can be diagnosed and begin treatment right away, if hypothyroid.

PEOPLE OF ALL AGES

No one can predict whether hypothyroidism will worsen. Subclinical (mild) hypothyroidism may never get worse or it may get worse over months or years. If people with autoimmune hypothyroidism also have high levels of anti-TPO antibodies, their hypothyroidism is more likely to worsen, although there is no way to predict how quickly. Anti-TPO antibodies attack the enzyme within the thyroid that helps thyroid cells make hormone. It is not known whether treating hypothyroidism prevents it from worsening.

SEVERE HYPOTHYROIDISM (MYXEDEMA)

The worse untreated hypothyroidism becomes, the less the body is able to cope with stressors like cold weather, infections or even minor surgery. Severe hypothyroidism is called
myxedema. Usually it takes years for hypothyroidism to reach the point of myxedema, but people who do not have a thyroid (because of surgery or radioactive iodine treatment) can progress to myxedema in months. In people with myxedema, the body slows to the point that it starts to shut down. At its worst, the person falls into a coma. To survive a myxedema coma, people need good supportive care in the hospital intensive care unit. Myxedema is now rare in developed countries.

KEEPING OTHER PEOPLE INFORMED

TELL YOUR FAMILY

Because thyroid disease runs in families, you should explain your hypothyroidism to your blood relatives and encourage them to get a TSH test. If it is normal, they should be retested if they develop symptoms, or at least every 5 years.

TELL YOUR OTHER DOCTORS AND PHARMACIST

Keep your other doctors and your pharmacist informed about your hypothyroidism and about the drug and dose with which it is being treated. If you start seeing a new doctor, tell the doctor that you have hypothyroidism and you need your TSH tested every year. If you see an endocrinologist, ask that copies of your reports be sent to your primary care doctor.

You do not need to wear a medical alert bracelet, but it would be wise to keep a card in your wallet that lists:
• Your name and contact information
• Your doctor's name and contact information
• That you have hypothyroidism and any other diseases or healthy conditions
• Your thyroxine brand name and dose

PARTNERSHIP BETWEEN YOU AND YOUR DOCTOR

The more you and your doctor work as a team, the healthier you will be.

YOUR JOBS

Because you will probably have hypothyroidism for the rest of your life, you have to be your own main caretaker. You cannot depend on your doctor to do all the work for you. You have to fill your prescriptions and take your pills every day. You have to make and keep your appointments for blood tests and doctor visits. When you go for visits, you have to tell your doctor how you are feeling and be honest in saying how often you miss your pills. Before you visit your doctor, write a list of all the things you want to ask or tell him or her so you do not forget.
YOUR DOCTOR’S JOBS

Your doctor should explain hypothyroidism to you and how it is treated. He or she should also answer any questions that you have and listen to your concerns. The doctor should take your symptoms into account when adjusting your thyroxine dose and give you your blood test results. Choose a doctor who keeps up to date about advances in the diagnosis and treatment of thyroid disease.

YOUR EMOTIONAL NEEDS

Many people are diagnosed with hypothyroidism after feeling sick for years or believing or being told their symptoms are "all in your head," "just stress," or "a normal part of aging."

Some people are so relieved finally to know what is wrong that they are eager to start treatment so they can begin to feel better. Other people are so exhausted and depressed by the time they are diagnosed that they do not believe they have the energy to work at getting better or may fear they will never feel well again.

It is important to be patient as you begin treatment—patient with yourself and the changes happening in your body, patient with your doctor, and patient with the people who are going through this with you. It can take weeks before the thyroxine starts working to a point that you begin feeling better and months before you and your doctor get the dose exactly right. But for most people, the effort is worthwhile. Most people treated with thyroxine feel better than they have in years.

LIVING WITH HYPOTHYROIDISM

There is no cure for hypothyroidism, and most people have it for life. Over time, your hypothyroidism may become more or less severe. As a result, your thyroxine dose may need to change. You have to make a lifetime commitment to treatment. You should never stop thyroxine treatment on your own. If you do, your symptoms will return.

If you take your pills every day and work with your doctor to establish the correct thyroxine dose, you should be able to keep your hypothyroidism completely controlled throughout your life. Your symptoms should disappear and the serious effects of low thyroid hormone should stop getting worse and should actually improve. If your hypothyroidism is well-controlled, it will not shorten your lifespan.

MANY QUESTIONS ABOUT HYPOTHYROIDISM REMAIN MYSTERIES

For example: Which genes increase people’s risk for thyroid disease? What triggers the start of thyroid disease? Why does the immune system attack the thyroid? These are among the questions that researchers, including members of the American Thyroid Association, are working hard to answer.
Medical Terms in this Booklet

**Addison’s disease:** permanent loss of function of the adrenal glands, which make essential steroid hormones for the body

**anemia:** too few of the red blood cells that deliver essential oxygen to the body's cells

**antibodies:** proteins that the body's immune system makes to invaders like bacteria and viruses

**anti-TPO antibodies:** in autoimmune thyroid disease, proteins that attack the thyroid peroxidase (TPO) enzymes that help the thyroid make hormone

**autoimmune disease:** any disease in which the body's immune system, designed to protect the body from viruses and bacteria, attacks a normal (healthy) part of the body

**autoimmune thyroiditis:** inflammation of the thyroid, caused by autoimmune disease

**atrophic thyroiditis:** a form of autoimmune thyroiditis in which the immune system's attack on the thyroid causes it to shrink and stop making thyroid hormone

**coma:** unconsciousness from which a person cannot be awakened

**congenital hypothyroidism:** hypothyroidism in a newborn baby

**cretinism:** mental and physical retardation caused by severe congenital hypothyroidism

**deficiency:** a lack; too little

**ectopic:** in the wrong place; an ectopic thyroid is usually in the tongue and/or upper neck

**endocrine gland:** any gland that produces and releases hormones directly into the blood; for example, the thyroid, pituitary, adrenals, and pancreas

**endocrinologist:** a medical doctor who specializes in endocrinology, the treatment of endocrine gland diseases like thyroid disease and diabetes

**enzyme:** protein that helps chemical processes take place within the body but does not get used up in the process; the major enzymes in the thyroid are peroxidases

**feedback loop:** a system in which A affects B, which in turn affects A again

**fetus:** a developing baby

**free T4:** the thyroid hormone T4 that circulates in the blood unattached to a protein and that can be taken up by cells in tissues

**free T4 index:** an estimate of the amount of free T4 in the blood

**gland:** an organ or tissue that makes and sends out a hormone or other substance

**goiter:** an enlarged thyroid, which can cause swelling in the front of the neck Graves’ disease: autoimmune hyperthyroidism, usually with goiter and eye symptoms Hashimoto’s thyroiditis (also called Hashimoto’s disease): autoimmune thyroiditis in which the immune system’s attack on the thyroid causes a goiter and, sometimes, hypothyroidism

**hormone:** substance, made by an organ or tissue, that affects the function of one or more other organs

**hyperthyroidism:** an overactive thyroid

**hypothyroidism:** an underactive thyroid

**I 131:** one of several forms of radioactive iodine; low-dose I 131 is used for medical testing and to destroy an overactive thyroid

**infiltrate:** to deposit an abnormal substance in a tissue

**immune system:** the body’s way of protecting itself from invaders like bacteria and viruses

**inflammation:** the body’s response to injured cells

**iodine:** chemical element that is an essential ingredient of thyroid hormone

**mcg:** unit of measure, abbreviation for "micrograms"; thyroxine doses may be measured in mcg (also written as ug); 50 mcg = .05 mg (milligrams)
metabolism: all the processes by which the body makes and uses energy and builds tissues
mild hypothyroidism (also called subclinical hypothyroidism): a T4 in the normal range, but a slightly high TSH of 4.0 to 10.0 mU/L, causing few or no symptoms
mU/L: unit of measure, abbreviation for "milliunits per liter"; TSH levels are measured in mU/L
myxedema: severe hypothyroidism; the brain, heart, lungs, kidneys, and other organs slow to the point that they cannot keep up critical functions like maintaining temperature, heart rate, blood pressure, and breathing
myxedema coma: often-fatal unconsciousness resulting from severe hypothyroidism
nodule: small abnormal mass or lump; nodules in the thyroid are very common, but few are cancerous
paresthesias: feeling of pins and needles in the hands and feet
pituitary gland: from its position in the base of the brain, the pituitary monitors most basic body functions and sends out hormones that control those functions, for example, the rate at which the thyroid makes hormone
polyglandular autoimmune syndromes: combinations of autoimmune diseases affecting both endocrine and non-endocrine organs and usually involving the thyroid
postpartum: after giving birth
premature ovarian failure: before the normal age for menopause, the ovaries' loss of ability to produce estrogen and release eggs, leaving a woman unable to become pregnant
radioactive iodine (also called radiiodine): iodine that has naturally or artificially been made radioactive; see "I 131" above
secondary hypothyroidism: hypothyroidism caused not by damage to the thyroid but by damage to the pituitary gland, preventing it from being able to tell the thyroid to make hormone
set point: the body's preferred level or range for a function; for example, the pituitary gland knows the body's normal T4 range (set point) and works to keep the T4 within that range
silent: not causing symptoms
subclinical ("mild") hypothyroidism (also known as mild hypothyroidism): a T4 in the normal range, but a slightly high TSH of 4.0 to 10.0 mU/L, causing few or no symptoms
supportive care: general medical care, such as nutrition and fluids, to help a person recover when no targeted treatment can improve the person's condition
suppressive treatment: thyroxine dose high enough to keep the TSH below normal
syndrome: a combination of symptoms
synthetic: made in a laboratory
T3: triiodothyronine, a hormone with 3 iodine molecules, made in small amounts by the thyroid and in larger amounts from T4 in other body tissues
T4: thyroxine, the main hormone made by the thyroid
thyroid: a gland, normally in the lower front of the neck, that makes and sends out the hormones T4 and T3 that regulate the metabolism of every cell in the body
thyroid hormones: T4 and T3, the products of the thyroid
thyroiditis: inflammation of the thyroid
thyroidologist: a medical doctor who specializes in the diagnosis and treatment of thyroid diseases
thyroid peroxidase (TPO) enzymes: enzymes within the thyroid that help thyroid cells make hormone
thyroid stimulating hormone (TSH): hormone that the pituitary gland makes and sends into the blood to tell the thyroid how much T4 and T3 to make
thyroxine: T4, the main hormone made by the thyroid; also, pills used to treat hypothyroidism by replacing the missing T4
trimester: three months; the nine months of a pregnancy are broken into three trimesters
TPO: thyroid peroxidase
TSH: thyroid-stimulating hormone

TO LEARN MORE
Visit the ATA web site, www.thyroid.org, to learn more about hypothyroidism. There you will find:
• names of thyroid specialists in your area,
• access to “Friends of the ATA” newsletter emailed to you with the latest thyroid news updates
• Clinical Thyroidology for Patients, a monthly publication describing the latest thyroid research,
• The most recent guidelines for the management of thyroid diseases and thyroid cancer,
• Links to the ATA Alliance for Patient Education -- organizations that help patients,
• And, current and up-to-date information and education about thyroid disorders.
